Q1

Binary search is $O(n)$ in the worst case because if the element is missing you may have to look at every cell to be sure. The recurrence just shows the best case is faster.

Q2

Greedy works. Exchange argument.

B11902007

羊念真

Q3

DP, $O(n^2)$.

Q4

True. Invariant: when BFS finishes layer d , every vertex at distance d has been discovered with $\text{dist} = d$. Base: layer 0 is $\{s\}$. Step: any v at distance $d+1$ has a neighbour u at distance d ; when u is dequeued v is discovered with $\text{dist } d+1$, and no earlier layer can reach v or its distance would be $< d+1$.
